Basis of Report

This document has been prepared by SLR Consulting Limited (SLR) with reasonable skill, care and diligence, and taking account of the timescales and resources devoted to it by agreement with Scottish and Southern Electricity Networks (SSEN) (the Client) as part or all of the services it has been appointed by the Client to carry out. It is subject to the terms and conditions of that appointment.

SLR shall not be liable for the use of or reliance on any information, advice, recommendations and opinions in this document for any purpose by any person other than the Client. Reliance may be granted to a third party only in the event that SLR and the third party have executed a reliance agreement or collateral warranty.

Information reported herein may be based on the interpretation of public domain data collected by SLR, and/or information supplied by the Client and/or its other advisors and associates. These data have been accepted in good faith as being accurate and valid.

The copyright and intellectual property in all drawings, reports, specifications, bills of quantities, calculations and other information set out in this report remain vested in SLR unless the terms of appointment state otherwise.

This document may contain information of a specialised and/or highly technical nature and the Client is advised to seek clarification on any elements which may be unclear to it.

Information, advice, recommendations and opinions in this document should only be relied upon in the context of the whole document and any documents referenced explicitly herein and should then only be used within the context of the appointment.

1.0 Introduction

SLR Consulting Limited (SLR) have been appointed by Scottish and Southern Electricity Networks ('SSEN') to provide a Drainage Strategy (DS), to support an outline planning application for the Netherton Hub Phase 1 hereafter known as the 'Site', on land at Flushing, Netherton, Aberdeenshire.

1.1 Project Background

The proposal is for the site to become a new Direct Current Sub-Station (DCSS), High Voltage Direct Current (HVDC) Converter Station and Alternating Current (AC) Sub-Station as part of the SSEN Netherton Hub allocation.

A Flood Risk Assessment has previously been undertaken for the site by Stantec (LT0000520STA-CIV-RPT-001, Jan 2024).

1.2 Site Location

The Site is located near the village of Flushing, adjacent to the A950 Longside Road, approximately 5.3km west of Peterhead. The Site is centred on an approximate Easting and Northing of 405439, 845891 and the nearest postcode is AB42 4TR.

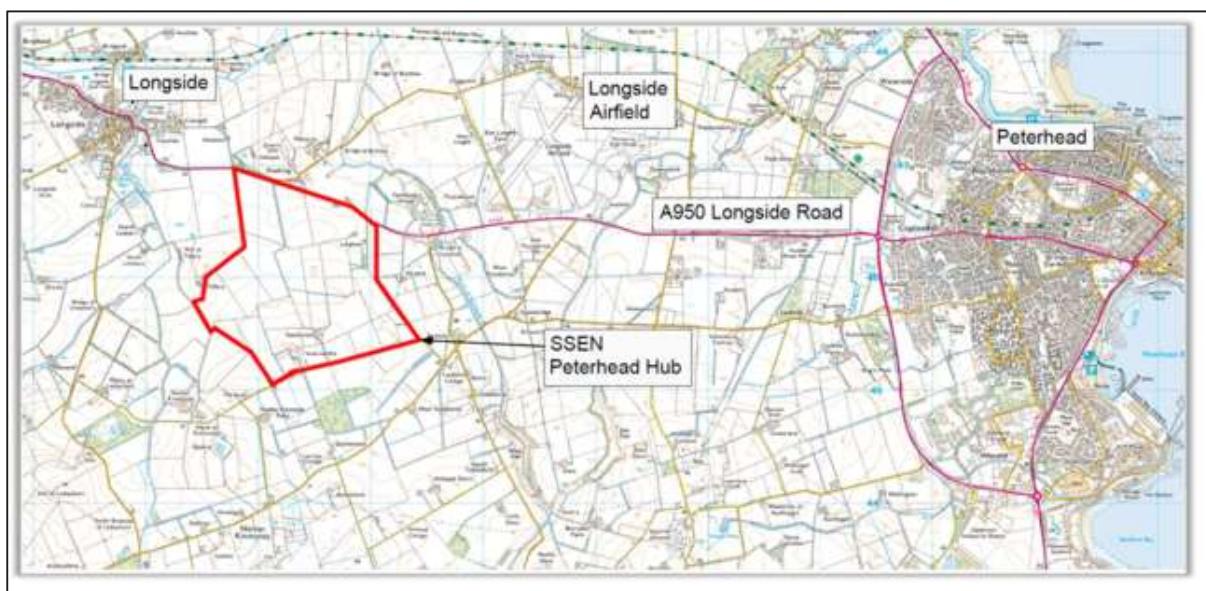

Figure 1 – Netherton Interconnector Hub Site Location Plan

1.3 Proposed Development

The proposed development plan (LT000052-SLR-CIV-LAY-019-01) shows the development to comprise 4 No. substation units of varying sizes constructed on development platforms at finished formation levels of between 44m AOD and 51m AOD. The scheme will include SUDS and landscape bunds, as well as general access infrastructure and other smaller ancillary structural units.

The Proposed Development Plan is enclosed within Appendix A.

1.4 Purpose of this Report

This assessment is to be undertaken in accordance with the standing advice and requirements of the Scottish Environment Protection Agency (SEPA) and the National Planning Framework 4 (NPF4).

Where the proposed works to which this report refers are materially changed following the issue of the report, SLR shall reserve the right to re-validate the findings and conclusions by undertaking appropriate further investigations at no cost to SLR.

The assessment will:

- Consider the impact the development may have elsewhere with regards to flooding,
- Consider design proposals to mitigate any potential risk of flooding determined to be present,
- Consider detailed drainage proposals to mitigate flood risk from the site;

The following documents, provided by the Client, have been reviewed;

- Drainage Strategy Report (December 2023) – LT000052-STA-CIV-RPT-001
- Flood Risk Assessment (July 2023) - LT000052-STA-CIV-RPT-002
- Drainage (Surface Water) plan “331201430-STN-18-XX-LAY-OD-003”
- Drainage (Foul) plan “331201430-STN-18-XX-LAY-OD-002”
- Envirocheck Reports, April 2023
- Mott Macdonald (Converter Platform) Outline Drainage Strategy, August 2023 – 103995-MMD-STND-XX-TN-C-0006-Rev 1
- SSEN Drainage Specification – SP-NET-CIV-502, July 2020
- Ardmore Point Utility Location Survey (September 2023) – AP2555/GPR/01

The following policy documents and government web publications have been consulted;

- Water Assessment and Drainage Assessment Guide by the Sustainable Urban Drainage Scottish Working party (SUDSWP)
- National Planning Framework 4 (NPF4)
- Aberdeenshire Local Development Plan
- SEPA Technical Flood Risk Guidance for Stakeholders
- SEPA Online Flood Maps
- Local Flood Risk Management Plan 2022
- CIRIA SuDS Design Manual, C753, 2015

2.0 Existing Site Details

2.1 History and Current Use

The Site encompasses 222 hectares of land, and is located west of Peterhead, to the southern edge of Flushing, Aberdeenshire, Scotland. The Site is centred on an approximate Easting and Northing of 405439, 845891 and the nearest postcode is AB42 4TR.

The Site is predominantly undeveloped greenfield land used for agriculture. Aberdeenshire Council classifies the Site as private farmland.

The northern site boundary sits adjacent the A950 Longside Road, while the rest of the site is bounded by other private agricultural properties.

Historic Map data from 1899, obtained as part of Envirocheck Landmark Report, April 2023 shows the site has predominantly remained undeveloped, with a small parcel of land along the southern boundary being developed into agricultural stores.

Figure 2 – Aerial Photograph (© Google 2024)

2.2 Existing Watercourses and Other Waterbodies

The following waterbodies have been identified within the Site and the surrounding area:

- An existing ditch, that runs from the centre of the Site to the northern boundary, has been identified by SEPA as a watercourse. This crosses the A950 via a 900mm sewer to a drain, which ultimately discharges to the Burn of Faichfield,
- The Burn of Faichfield, runs west to east adjacent, the northern most boundary. The burn is approximately 360m north of the main site area; and,
- The Burn of Ludquharn runs south to north, adjacent the western most boundary. The burn is approximately 500m west of the main site area.

2.3 Existing Utilities

A utility search was conducted by Atkins on behalf of the client in January 2023. The search identified the following infrastructure within the site;

- A SSEN Overhead electricity line runs through the south area of the site to the existing buildings.
- A National Grid Gas Transmission National-High Pressure main runs through the north area of the site, crossing the north and northwest site boundary line.
- Two BT overhead cables supply the farm buildings to the south of the site.

The SSEN and BT overhead electricity lines will be removed as part of the works. The gas main will be maintained with an easement.

No public foul, surface or combined sewers were identified within the site.

2.4 Topography

A Utility and Topographical Survey was conducted by Admore Point in September 2023, and is enclosed within *Appendix B*.

The survey indicates the site topography generally falls towards the north of the site. From a levels perspective the site has two distinct areas. The western area to the south of site decreases down slope with a gradient towards the Burn of Ludquharn. The elevation change in this part of the site is from approximately 65.5m AOD at the top of the hill in the southwest corner of the site, to 35.0m AOD at a central point of the west boundary.

The central and eastern areas of the site grade from the hill in the southwest corner, at approximately 65.5m AOD, to the north boundary with levels varying between 30.5m and 31.5m AOD across the site boundary.

There is a small area in the southeastern corner of the site that does not follow the general site convention. This area grades easterly from a localised high point near the southern boundary, approximately central, at 56.0m AOD, to the southeast corner with an approximate level 48.5m AOD.

The existing contours and estimated existing watersheds are shown below within Figure 3.

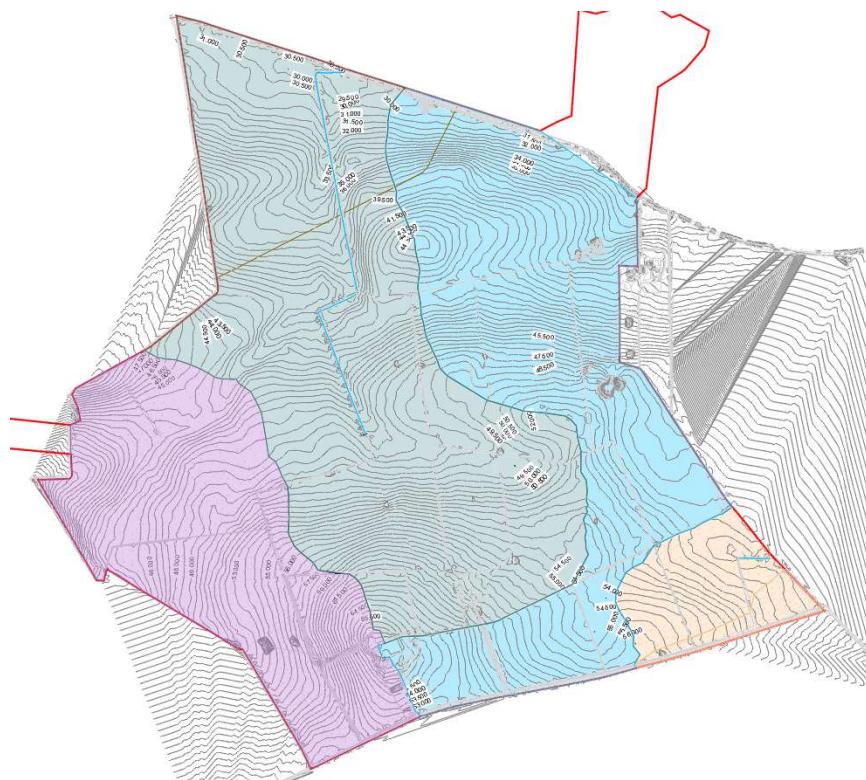

Figure 3 – Topographical Survey with demarcation of assumed existing watersheds

The site is bound to the North by the A950, to the south by an unnamed local road and by fields to the eastern and western boundaries. There are several existing properties/buildings within the site boundary which are to be demolished as part of the works.

2.5 Geology

The British Geological Survey (BGS) information available online has identified the following geological succession underlying the site:

- Superficial Deposits – Banchory Tilly (Gravelly and sandy Diamicton)
- Bedrock – Forest of Deer Pluton (Melagranite, Biotite), Crinan Subgroup and Tayaliich Subgroup (Undifferentiated – Sempelite, Pelite and Psammite)

The geological strata underlying the site has been discussed in detail in the SLR Earthworks Strategy Report.

3.0 Surface Water Strategy

3.1 Pre-development Runoff

The site is predominantly undeveloped field land and as such is classified as 'greenfield'. Rainfall will currently infiltrate into the ground where geological and hydrogeological conditions allow, and then runoff once the infiltration capacity of the ground has been exceeded. The runoff will then flow across the Site, directed by the existing terrain, and discharge out of site.

Based on topographic survey levels the Site currently discharges in four main directions. These existing watersheds are detailed below in Table 1 and within Figure 4.

Watershed	Area (Hectares)	Discharge Summary
A	64.646	Runoff will flow across the north boundary and will ultimately discharge to the Burn of Faichfield.
B	89.955	Overland flows, collected by an existing ditch running through the site, discharge via a 900mm diameter sewer crossing the A950. This ultimately discharges to the Burn of Faichfield.
C	46.645	Runoff is directed across the west boundary to a tributary ditch of the Burn of Ludquharn.
D	12.044	Runoff is directed across the southeast site boundary. Based on currently available level information it is believed these flows would ultimately discharge to the Burn of Faichfield at a point east of the Site

Table 1: Existing Watershed Summary

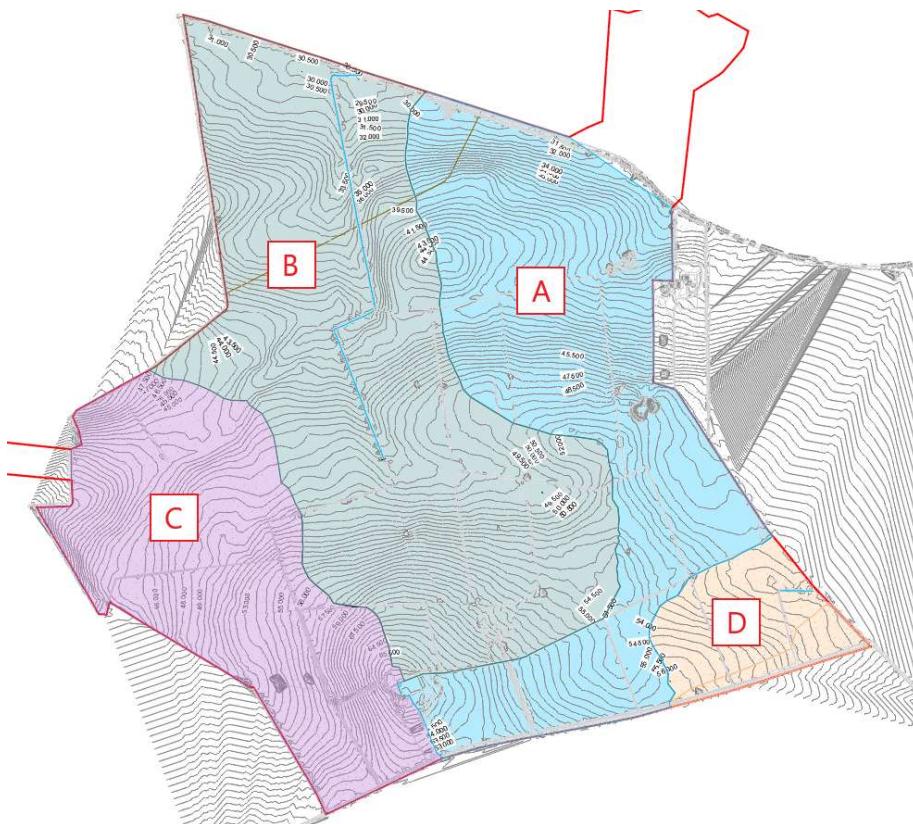

Figure 4 –Existing Watersheds

The existing QBar rate has been calculated, using FEH point data within Causeway Flow modelling software, for each watershed and is detailed in Table 2 below.

Watershed	Area (Hectares)	Qbar (L/s)
A	64.646	242.3
B	89.955	320.9
C	46.78	181.6
D	12.044	46.9
Developed Site Area	213.29	669

Table 2: Qbar Summary

3.2 Post-development Runoff

In accordance with the NPF4, local guidance, consultation with relevant stakeholders and based on the Greenfield designation, as stated in the existing site description, the proposed site discharge rate will be restricted to the 'Greenfield' Qbar rates.

Discharge rates are subject to discussion and approval by SEPA.

The SEPA "Climate change allowances for flood risk assessment in land use planning- Version 4" publication has been reviewed, which advises the Site is within the 'North-East Scotland' River Basin Region. As the catchment is less than 30km², the 'Peak Rainfall Intensity' allowance should be used, which for this region is 37% (Table 2: Peak rainfall intensity allowances by River Basin Region).

The publication advises that for developments that are likely to be 'particularly vulnerable to climate change', additional sensitivity testing should be carried out. For the region, an increased climate change allowance of 55% would be advised.

Although the development is 'vulnerable' from a planning designation perspective, it is not considered to be 'particularly vulnerable to climate change' as there are no tidal waterbodies within the vicinity.

3.3 Post-development Attenuation Volume

In restricting the flows from the development to greenfield rates, there will be a requirement to provide attenuation to accommodate flows for the required storm periods.

The SSEN Drainage Specification (SP-NET-CIV-502), with reference to the ENA Technical Report 138, identifies that the levels of flood protections for the site, as a minimum shall include,

- 1 in 200-year rain-fall return period protection for 'operational' areas
- 1 in 1000-year rain-fall return period protection for 'critical equipment'
- 1 in 200-year rain-fall return period protection for off-site flooding.

Then SSEN Specification does not identify the requirement for the 1 in 30-year event, however it is a planning requirement and considered robust to design for no flooding in the 1 in 30-year event.

Based on this, the development will be designed to provide attenuation to accommodate flows for up to the 1 in 200-year event with a climate change allowance of 37%.

The 1 in 1000-year return period will be also be simulated and reviewed to ensure no flooding occurs to areas containing critical equipment.

The required volume of attenuation for each catchment has been calculated using Causeway Flow, based on areas measured from the proposed development plan. A summary of the required attenuation and assumed variables are detailed in Table 4 and within Figure 5 below.

Watershed	Basin ID	Proposed Catchment Area	Equivalent Impermeable Area (Ha)	Qbar (L/s)	Required Attenuation Volume (m ³)
A	East Basin	96.358	65.462	242.3	89,500
B	North West Basin	53.178	25.394	320.9	27,500
C	West Basin	63.752	38.239	181.6	39,500
D	The runoff from Watershed D will be collected and combined with runoff from Watershed A and attenuated within the East Basin				

Table 3: Attenuation Volumes Summary

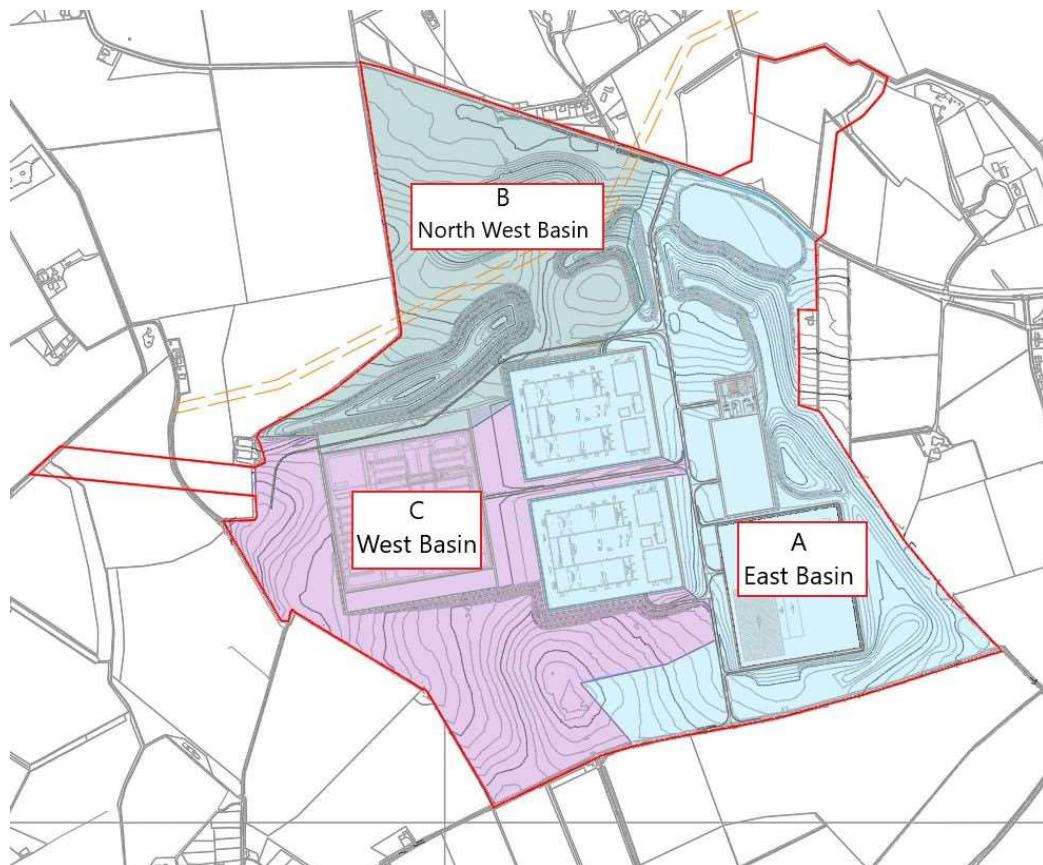

Figure 5 –Proposed Catchments

The 'Equivalent Impermeable Area' values have been determined based on applying a runoff percentage to each of the land types within the proposed catchments. The runoff percentages for each land type are as follows.

- 100% - Roads and platforms

Although the platforms are proposed to be constructed from permeable aggregate, it was advised by the Operations Manager for the development that these areas should be considered impermeable.

- 47% - Landscape areas

HR Wallingford advises a ‘Soil Percentage Runoff (SPR)’ value of 47% for this area. SPR is ‘assumed to be the proportion of rainfall that contributes to surface water runoff and is based on analysis of data from flood events and adjusted for rainfall and catchment properties’.

It is considered a conservative approach to use SPR values as it does not account for absorption of runoff by proposed vegetation. The landscape proposals have not been developed at this stage so the SPR value will be applied. Once the proposed vegetation plan is known, the runoff assumption will be revised, which will impact the required attenuation volume.

Any phasing proposed for the development may require temporary or staged flow restriction and attenuation.

The SEPA online Flood Maps identify that there is an area within the ‘North West’ catchment (Existing Watershed B) that is at high risk of pluvial flooding, meaning this area has a 10% chance of flooding each year. Figure 5 below shows the extent of high risk flooding in relation to the site extents.

The flooding area occurs along the north boundary of the Site and the A590 highway, and based on the topographic survey the area is a low point which coincides with an existing discharge point off site, the existing 900mm diameter pipe.

The drainage strategy proposes to significantly reduce the catchment size upstream of the potential flooding zone from 90.18Ha (Table 2) to 53.29Ha (Table 3) as well as provide an attenuation feature to formally contain flows for the 1 in 200-year plus climate change event.

This should not only significantly reduce pluvial flooding to the existing area but will ease the demand on the Burn of Faichfield downstream that is currently shown to have fluvial flooding.

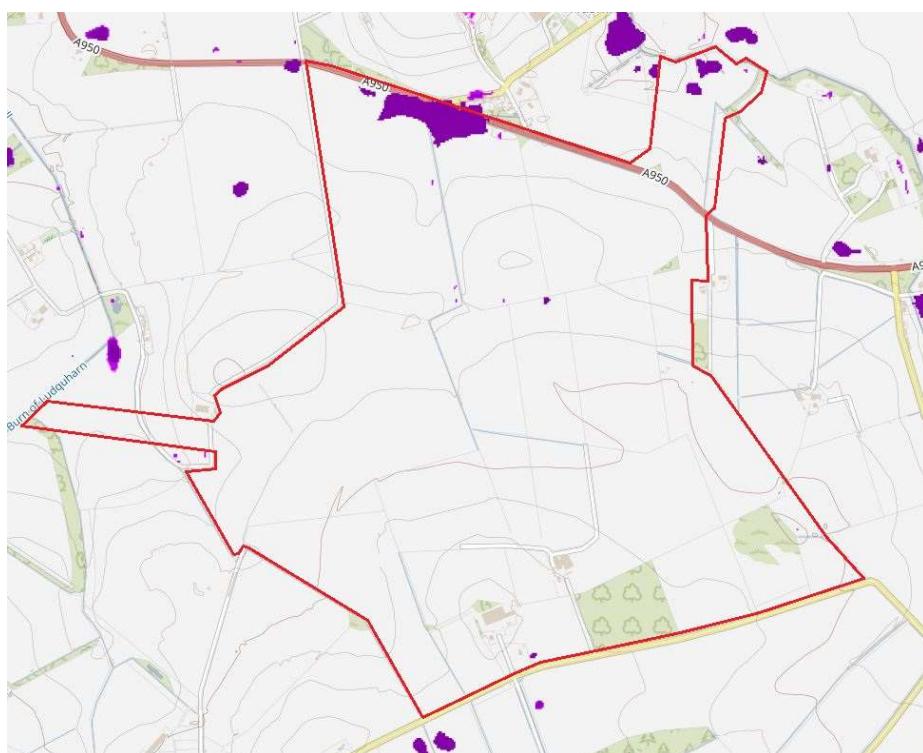

Figure 5 –SEPA Pluvial Flood Map (2024)

3.4 Sustainable Drainage Systems (SuDS)

Recent changes to guidance and opinion within the industry have led to greater focus on Sustainable Drainage Systems (SuDS) and long-term sustainable development. In addition, the industry is well versed to controlling the volume of runoff via managed outfalls, the use of SuDS systems creates an environment where the quality of the water is also managed and improved.

CIRIA C753 – the SuDS Manual has set out objectives to minimise the impacts from the development on the quantity and quality of the runoff. The guidance refers to the SuDS Management Train.

3.4.1.1 The SuDS Management Train

The ‘Management Train Approach’ should be central to the surface water drainage strategy of a proposed site. The main objective is treatment and control of runoff as near to source as possible, thus protecting downstream habitats and further enhancing the amenity value of the site. This concept uses a hierarchy of drainage techniques to incrementally reduce pollution, flow rates and volumes of storm water discharge from the site, and is as follows:

- i. **Prevention** – The use of good site design and housekeeping measures to prevent runoff and pollution and includes rainwater reuse.
- ii. **Source Control** – Control of runoff at source or as close to source as possible (e.g., cellular storage, petrol interceptors, flow attenuation devices).
- iii. **Site Control** – Management of water in a local area and can include below ground storage/attenuation, detention basins, tanks, oversized pipes.
- iv. **Regional Control** – Management of water from a site or various sites and can include wetlands and balancing ponds.

The drainage techniques for this development will seek to include, where possible, prevention, source control and site control measures.

3.4.1.2 The SuDS Design Philosophy

The SuDS philosophy for a development site is the promotion of Prevention, Source Control and Site Control Techniques.

The following design philosophy is proposed:

- Surface water treatment using the ‘Management Train’ approach to remove and isolate contamination at all SuDS facilities prior to conveyance to the proposed end of site attenuation feature.
- Surface water discharge to be attenuated to greenfield runoff rate (defined as Qbar).
- Prevention measures, for example the inclusion of water butts.
- Site Control features, in the form of above-ground attenuation storage, to accommodate the additional surface water runoff generated by the development site.
- Provision of suitable treatment features in line with Pollution Prevention Guidance 3 criteria (where applicable).

Varied SuDS methods are summarised in the table below to assess and establish which are most feasible for the proposed post development site.

Table 4: SuDS Feasibility Assessment

SuDS Method	Feasibility, Given Site and Project
Green & Blue Roofs	Green roofs are areas of living vegetation, installed on the top of buildings, for a range of reasons including visual benefit, ecological value, enhanced building performance and the reduction of surface water runoff. A Blue roof is a roof design that is explicitly intended to store water. These features provide source control and assist in pollution prevention, however they do require comparatively more maintenance than other SUDS while providing less storage capacity per square meter. Green & Blue roofs could be incorporated on buildings where roof pitch and available space allows, at the detailed design stage. For now, the strategy focuses on using other SUDS features, such as basins and swales.
Basins and Ponds – Above Ground Storage	Basins and ponds increase biodiversity and amenity of the area; provide attenuation; and improve water quality. This method does occupy large areas of developable land and needs to be constructed at the lower levels of the site. Detention basins will be incorporated within the landscape areas to attenuate runoff from surrounding areas and for exceedance flows.
Swales	Swales are shallow, flat bottomed, vegetated open channels designed to convey and treat surface water runoff. When incorporated into the site design they can be used to enhance the natural landscape and provide aesthetic and biodiversity benefits. Swales are proposed throughout the Site to capture, convey, and attenuate runoff from the highways and landscape areas and for exceedance flows. Standard swales are proposed where grades allow and under-drained swales with filter systems are proposed where the site levels are flat.
Filter Strips	Filter strips are uniformly graded and gently sloping strips of grass or other dense vegetation that are designed to treat runoff from adjacent impermeable area by promoting sedimentation, filtration and infiltration (where acceptable). At low to moderate velocities, filter strips effectively reduce particulate pollutant levels. Without infiltration, filter strips require an underground, perforated pipe network. In order to minimise the amount of buried systems, swales have been proposed adjacent highways to keep runoff flowing overland. Where levels dictate, the swale systems will be under-drained and a filter strip system will be incorporated beneath.
Bioretention Systems (Incl. Raingardens)	Bioretention systems (including rain gardens) are shallow landscaped depressions that can reduce runoff rates and volumes and treat pollution through the use of engineered soils and vegetation. They are generally used for managing and treating runoff from frequent rainfall events. Where larger events are directed to the system, consideration of the impact of design velocities on the system will be required. It is often more appropriate to pass runoff from extreme events directly to drainage components further downstream. As the development is being designed for extreme events and due to the high maintenance requirements, it is not considered feasible to incorporate these systems.
Permeable Paving	Permeable paving is a form of pavement construction that allows road runoff to infiltrate through the surface layer to underlying treatment and storage media. They are an efficient means of managing and treating surface water runoff close to its source. Permeable paving is most commonly proposed within parking areas, and it is recommended that it

SuDS Method	Feasibility, Given Site and Project
	is incorporated when developing the drainage design for Operations Building carpark at the detailed design stage.
Infiltration Devices	Soakaway testing was conducted on site but was not able to be completed due to poor infiltration rates. As such infiltration devices will not be feasible.
Tanked/Geocellular Attenuation Systems	Tanked/geocellular attenuation systems provide high storage capacity and can be incorporated within road pavements and under landscaping. However, they do not provide runoff treatment or improve amenity and biodiversity so other forms of SUDS should be used where possible.

3.5 Drainage Hierarchy

Current guidance (CIRA SuDS Manual) recommends the use of the Drainage Hierarchy when developing a surface water strategy for any site. The purpose of the Drainage hierarchy is to ensure consideration is firstly given to sustainable methods of discharge of surface water runoff by sustainable methods such as infiltration which promotes the ‘at source’ methodology set out in the SuDS Management Train principals.

“Generally the aim should be to discharge surface runoff as high up the following hierarchy of drainage options as reasonably practicable:

- 1 into the ground (infiltration)
- 2 to a surface water body,
- 3 to a surface water sewer, highway drain, or another drainage system,
- 4 to a combined water sewer”

As part of this drainage strategy each management method is assessed for suitability.

Table 5 summarises the options for the surface water disposal:

Table 5: Surface Water Disposal

Surface Water Disposal	Potential	Description
Infiltration	X	As part of the Site ground investigation, soakaway testing was conducted. Tests must be carried out in accordance with BRE 365 and the test was not able to be completed. Water within the test holes did not drain within the given timeframe and infiltration rates were not able to be determined. Infiltration as a discharge method is therefore deemed unfeasible for this site.
Water body	✓	The site currently discharges to two water bodies, the Burn of Ludquharn and the Burn of Faichfield. Discharge or change of discharge condition is subject to approval by SEPA
Public Surface Water Sewer	X	A utility search was conducted by Atkins on behalf of the client in January 2023. The search identified that there were no public surface water sewers within the vicinity of the site
Public Combined Water Sewer	X	The Atkins utility search identified that there were no public combined sewers within the vicinity of the site

Based on the information provided above the preferred method of surface water disposal is to a waterbody, subject to approval by SEPA, and will be the basis of the Proposed Surface Water Drainage Strategy.

3.6 Treatment/Water Quality

Treatment of surface runoff that discharges to the water environment is a SEPA requirement in accordance with Regulatory Method (WAT-RM-08) for the regulation of urban drainage.

As discussed above, there has been a recent push to improve the quality of water discharge. The CIRIA SuDS Manual C753 (2015) provides a simple framework named the ‘SuDS Indices Method’ to provide guidance on the level and method of treatment recommended for different scenarios. This approach can be categorised into three key steps:

- Allocate suitable pollution hazard indices for the proposed land use (Figure 5),
- Select SuDS with a total pollution mitigation index (Figure 6) that equals or exceeds the pollution hazard index,
- Where the discharge is to protected surface waters or groundwater, consider the need for a more precautionary approach.

Where the mitigation index of an individual component is insufficient, two components (or more) in series will be required, where:

$$\text{Total SuDS mitigation index} = \text{mitigation index}_1 + 0.5 \times (\text{mitigation index}_2)$$

A factor of 0.5 is used to account for the reduced performance of secondary or tertiary components associated with already reduced inflow concentrations.

TABLE 26.2 Pollution hazard indices for different land use classifications

Land use	Pollution hazard level	Total suspended solids (TSS)	Metals	Hydro-carbons
Residential roofs	Very low	0.2	0.2	0.05
Other roofs (typically commercial/industrial roofs)	Low	0.3	0.2 (up to 0.8 where there is potential for metals to leach from the roof)	0.05
Individual property driveways, residential car parks, low traffic roads (eg cul de sacs, homezones and general access roads) and non-residential car parking with infrequent change (eg schools, offices) ie < 300 traffic movements/day	Low	0.5	0.4	0.4
Commercial yard and delivery areas, non-residential car parking with frequent change (eg hospitals, retail), all roads except low traffic roads and trunk roads/motorways ¹	Medium	0.7	0.6	0.7
Sites with heavy pollution (eg haulage yards, lorry parks, highly frequented lorry approaches to industrial estates, waste sites), sites where chemicals and fuels (other than domestic fuel oil) are to be delivered, handled, stored, used or manufactured; industrial sites; trunk roads and motorways ²	High	0.8 ²	0.8 ²	0.9 ²

Notes

- 1 Motorways and trunk roads should follow the guidance and risk assessment process set out in Highways Agency (2009).
- 2 These should only be used if considered appropriate as part of a detailed risk assessment – required for all these land use types (Table 4.3). When dealing with high hazard sites, the environmental regulator should first be consulted for pre-permitting advice. This will help determine the most appropriate approach to the development of a design solution.

Figure 5: Pollution Hazard Indices for land use classification (Table 26.2 the CIRIA SuDS Manual 2015)

TABLE 26.3 Indicative SuDS mitigation indices for discharges to surface waters

26.3

Type of SuDS component	Mitigation indices ¹		
	TSS	Metals	Hydrocarbons
Filter strip	0.4	0.4	0.5
Filter drain	0.4 ²	0.4	0.4
Swale	0.5	0.6	0.6
Bioretention system	0.8	0.8	0.8
Permeable pavement	0.7	0.6	0.7
Detention basin	0.5	0.5	0.6
Pond ⁴	0.7 ³	0.7	0.5
Wetland	0.8 ³	0.8	0.8
Proprietary treatment systems ^{5,6}	These must demonstrate that they can address each of the contaminant types to acceptable levels for frequent events up to approximately the 1 in 1 year return period event, for inflow concentrations relevant to the contributing drainage area.		

Notes

- 1 SuDS components only deliver these indices if they follow design guidance with respect to hydraulics and treatment set out in the relevant technical component chapters.
- 2 Filter drains can remove coarse sediments, but their use for this purpose will have significant implications with respect to maintenance requirements, and this should be taken into account in the design and Maintenance Plan.
- 3 Ponds and wetlands can remove coarse sediments, but their use for this purpose will have significant implications with respect to the maintenance requirements and amenity value of the system. Sediment should normally be removed upstream, unless they are specifically designed to retain sediment in a separate part of the component, where it cannot easily migrate to the main body of water.
- 4 Where a wetland is not specifically designed to provide significantly enhanced treatment, it should be considered as having the same mitigation indices as a pond.
- 5 See Chapter 14 for approaches to demonstrate product performance. A British Water/Environment Agency assessment code of practice is currently under development that will allow manufacturers to complete an agreed test protocol for systems intended to treat contaminated surface water runoff. Full details can be found at: <http://tinyurl.com/qf7yu7>
- 6 SEPA only considers proprietary treatment systems as appropriate in exceptional circumstances where other types of SuDS component are not practicable. Proprietary treatment systems may also be considered appropriate for existing sites that are causing pollution where there is a requirement to retrofit treatment. SEPA (2014) also provides a flowchart with a summary of checks on suitability of a proprietary system.

Figure 6: Indicative SuDS Mitigation indices (Table 26.3 the CIRIA SuDS Manual 2015)

The Simple Index Approach (SIA) Tool (MS Excel) can be used to determine the effectiveness of the proposed SuDS in providing suitable mitigation indices to exceed that of the pollution hazard index. Table 6 shows how the proposed SuDS satisfy the requirements.

Table 6: Simple Index Approach Summary

Land Use	Pollution Index			Mitigation Index				Suitability
	TSS	Metals	Hydrocarbons	Prop. SuDS	TSS	Metals	Hydro.	
Non-residential parking with infrequent changes	0.5	0.4	0.4	Permeable Paving	0.7	0.6	0.7	Sufficient
Other roofs (Typically commercial/industrial roofs)	0.5	0.4	0.4	Swale	0.5	0.6	0.6	Sufficient
Commercial yard and delivery areas, non-residential car parking with frequent change (eg. Hospitals, retail) all roads except low traffic roads and trunk roads/motorways	0.7	0.6	0.7	Swale + Detention Basin	0.5 + 0.5(0.5) = 0.75	0.6 + 0.5(0.5) = 0.85	0.6 + 0.5(0.6) = 0.9	Sufficient

The SSEN Drainage specification advises additional measures for pollution control specific to the substation platforms.

- An interceptor will be required downstream of the oil sump required on the platform,
- Swales and basins receiving discharge from an oily water mitigation system need to be lined to prevent infiltration,
- Swales need to be visible from the platform in order to monitor pollution,
- Sampling points need to be incorporated downstream of the swale or basin prior to discharge entering the water environment.

The above criteria will need to be considered, in conjunction with the proposed levels strategy and platform designs within the detailed design stage.

It is recommended that shutdown valves be included in the basin design in order to prevent contaminated runoff leaving site in the event of a pollution incident. This will be included in detailed design.

3.7 Proposed Surface Water Drainage

The proposed Drainage Strategy General Arrangement Plan is enclosed within *Appendix C*.

The development shall be designed in accordance with current best practice to provide adequate capacity to not allow flooding out of the network for the critical 1 in 30-year storm event and flood water generated for up to the critical 1 in 200-year plus climate change storm event shall be constrained within the areas on site so as not to cause damage to buildings, essential services, adjoining developments and services.

Runoff from highways and landscaped area will be collected and conveyed by a series of swales. Where flat levels dictate, sections of the swale network will need to be under-drained in order to convey flows at a self-cleansing velocity.

The platforms will be drained by a separate system, designed by others, and runoff will be conveyed to a single point where it will discharge to the site wide drainage system. Due to the deep level constraint imposed by the platform infrastructure, the runoff will need to be conveyed across site in a below ground pipe network. North of the platform development area, the topography allows for the 'East' below ground network to arise and combine with the overland swale network.

Runoff from each catchment is conveyed to a final detention basin for attenuation prior to a flow restriction device. Due to its efficiency in reducing upstream storage requirements, a proprietary vortex flow device is recommended. A 'Hydro-Brake' (Hydro International) is currently used for modelling purposes.

Alternative flow restriction devices, such as V-notch weirs, will be investigated at detailed design stage and a comparison of required storage volumes will be presented.

Following restriction, runoff from the 'East' and 'West' catchments will be conveyed across land to their respective discharge points into the Burns of Faichfield and Ludquharn. Restricted runoff from the 'North West' catchment will discharge to the existing 900dia road crossing south of the A590, as per existing conditions.

The SSEN Drainage Specification (SP-NET-CIV-502) advises that the system shall be designed such that 'operational' areas are protected, and off-site flooding does not occur for the 1 in 200-year rain-fall return period.

The current drainage models shows that;

- no flooding occurs for the 1 in 30-year return period
- no flooding occurs off-site occurs for the 1 in 200-year return period
- no flooding occurs to the operation areas for the 1 in 200-year return period.

The 'East' network experiences a volume of flooding (circa 600 cubic meters) in an area south of the 400KV AC Substation platform. This is due to the steep change in elevation in the swale adjacent the entry of the access road, meeting a long flat section. The change point is vulnerable to overtopping due to a build-up of head and its level relative to the surrounding area. This flood volume will overtop the swale in extreme events and spill out over the landscape area to the south where it is constrained by the proposed topography. It is deemed that the area south of the swale and between the red line boundary has sufficient space to enable the above flood volume to be spread over an acceptable area and depth. Allowing for a suitably controlled flooding area in the most extreme events. Additional capacity could be provided in the form of basins or depressions to mitigate the flooding in this area.

The 'North West' network experiences a volume of flooding (circa 300 cubic meters) in the middle of the catchment, south of northern bund where the existing ditch is diverted to the east. The quick change in direction to navigate around the proposed bund creates a point vulnerable to overtopping from high velocities experienced during extreme return periods. The flood volume will overtop the existing ditch and will be conveyed by the proposed terrain to a downstream swale or the detention basin. The point of flooding and its overland flood path does not affect any proposed development area, platforms or highways.

The drainage design has currently been based on point loading high level catchments into the network which demonstrates a 'worse case' scenario. At detailed design stage the catchments and network will be further developed to improve efficiencies and in principle, reduce the burden on the downstream network and alleviate flooding where possible.

3.7.1 Proposed SuDS/Attenuation Features

Based on consultation with the client and foreseen maintenance issues, there is a preference for each catchment to be attenuated within a single feature.

Due to the required proposed site levels and large volumes generated by overland subcatchments, a single feature is not feasible for the 'East' and 'West' networks. Relatively small intermediate detention basins are proposed at key points in the network to slow and attenuate runoff and contain flooding that would otherwise occur at low points and points of restriction. This practice reduces velocities and the diameters of the downstream pipe network.

The final attenuation feature for each catchment is a large detention basin.

Detention basins are landscaped depressions that are normally dry except during and immediately following storm events. Detention basins can be vegetated depressions that can provide treatment when designed to manage regular flows. Where the basin is vegetated, the soil surface can absorb some runoff, so can be used to support the prevention of runoff from the site for small rainfall events. The principal water quality benefits of vegetated detention basins are associated with the removal of sediment and buoyant materials, but levels of nutrients, heavy metals, toxic materials and oxygen-demanding materials may also be significantly reduced. (CIRIA 2015).

Each basin is designed to be a maximum 2.6m deep, with 1 in 3 side slopes in line with CIRIA guidance. The basins have been sized such that the water level does not exceed 2m for the 1 in 200-year + 37% climate change event and a 600mm freeboard is allowed. Due to groundwater level issues on the site, it is proposed that the basins are lined to prevent ingress.

Due to the size of the ‘East’ basins and required relatively flat invert level grade (1in 500), it is recommended that low flow channels be incorporated at detailed design to ensure flows are conveyed to the outfall during low rainfall events.

The current strategy for the ‘West’ network shows a large final detention basin adjacent the west site boundary. Due to the level difference between the DC Switching Station platform and the site boundary, a terraced feature is proposed. This not only allows more runoff to be attenuated across a steep grade but provides additional treatment as runoff will flow through a series of features. The design of this will be coordinated with the earthworks design during the detailed design stage. Additional intermediate basins or swale widening can also be proposed upstream in order to reduce the volume required at the discharge point.

Building roof runoff forms a significant portion of the runoff produced on the Converter Station platforms. Consideration should be given to the inclusion of a rainwater harvesting systems at detailed design stage in order to provide additional attenuation and to increase the time of entry into the downstream network.

3.7.2 Exceedance

The surface water drainage network has been designed to accommodate runoff for up to the 1 in 200-year plus climate change event, within the site boundary.

In the event of rare extreme rainfall events, the capacities of the sewers, waterbodies and other drainage systems may become exceeded.

An overland flow analysis should be undertaken at the detailed design state using finished site levels to determine where overland flows will be routed in extreme flood events. This analysis should conclude that proposed buildings are not at risk of flooding.

3.7.3 Proposed Outfalls

The current drainage strategy is based on the feasibility of discharging to three locations, the existing 900mm diameter pipe crossing the A590; the Burn of Faichfield at a point north of the Site; and the Burn of Ludquharn at a point west of the Site.

The ‘North West’ network is proposed to discharge to the existing 900mm diameter pipe crossing the A590. An asset survey (Nov 2002) was provided by Aberdeenshire Council which showed a 900mm diameter pipe crossing the A590 highway. The survey indicates the crossing is 1000mm deep but does not specify whether this depth is to the soffit or invert of the 900mm pipe. As it is unlikely the crossing was constructed with 100mm cover, it is assumed that the invert of the pipe is 1.9m deep. Based on topographic levels for the area, the IL would be approximately 27.99m AOD. Prior to detailed design the existing crossing will need to be surveyed to accurately determine the location; invert; diameter; and grade of the crossing.

The ‘East’ network is proposed to discharge to the Burn of Faichfield at a point north of the Site. Level information for the connection point is currently unknown. Based on SEPA flood map information a connection level of 24.0m AOD has been proposed. This level will need to be confirmed prior to detailed design.

SEPA flood maps for the area indicate that the point of connection proposed for the ‘East’ network is subject to fluvial flooding. Initial investigation of the flood maps indicates a flood level of approximately 25.5m AOD and as such, the network model has been designed with

a fully surcharged outfall. Due to the Site being significantly higher than the proposed Burn connection point, there will be sufficient head generated within the development to ensure continued discharge from the site during all storm events.

It is recommended that further hydrological investigations are undertaken for the wider area to accurately determine the anticipated flood level of the Burn of Faichfield for the 1 in 200-year rainfall event, prior to detailed design.

The 'West' network is proposed to discharge to the Burn of Ludquharn at a point west of the Site. Based on level information from Google Earth, the connection point to the Burn of Ludquharn is approximately 10m lower than the Site development area. This assumption has been used for modelling purposes but levels will need to be confirmed prior to detailed design.

3.7.4 Approvals

Approval will need to be sought from SEPA for the following items;

- Discharge rate and location to the Burn of Faichfield and Burn of Ludquharn
- Discharge of treated foul runoff to the Burn of Ludquharn
- Attenuation Strategy including Detention basin design
- Diversion and or realignment of the existing ditch within the 'North West' catchment

It is recommended that consultation be undertaken with SEPA at the earliest opportunity to ascertain an agreement in principle in order to avoid delays to the design schedule.

3.8 Maintenance

A full SUDS maintenance plan should be produced as part of the detailed drainage design and the precise requirements would depend on manufacture specification of the final design.

The maintenance of the drainage network will be the responsibility of SSEN.

An outline of the typical maintenance requirements of each proposed SUDS feature is provided below.

3.8.1 Detention Basins, Swales and Vortex Flow Control Devices

The anticipated maintenance and management for the detention basin and vortex flow control (VFC) associated with the basin is outlined in Table 7.

Table 7: Typical Detention Basin, Swale and VFC Maintenance Requirements

Maintenance Schedule	Required Actions	Minimum Frequency
Regular Maintenance	Remove litter and debris removal	Monthly
	Cut grass in and around basin	Half yearly (Spring – before nesting, and autumn)
	Manage other vegetation and remove nuisance plants	Monthly (or as required)
	Inspect inlets, outlets and overflows for blockages, and clear if required.	Monthly

Maintenance Schedule	Required Actions	Minimum Frequency
Annual Maintenance	Inspect banksides, liner, structures, pipework etc. for evidence of physical damage.	Monthly
	Inspect inlets and facility surface for silt accumulation. Establish appropriate silt removal frequencies.	Monthly (for first year), then annually or as required
	Check any penstocks and other mechanical devices.	Annually
	Tidy all dead growth before start of growing season.	Annually
	Remove sediment from inlet, outlets and forebay.	Annually (or as required)
	Manage wetland plants in outlet pool – where provided.	Annually
	Removing sedimentation that has become entrained into the outflow	Six monthly or as required
	Ensure there are no leakage issues associated with the VFC	Six monthly or as required
Occasional Maintenance	Check VFC for sedimentation, or other blockages and flow bypassing	Six monthly
	Re-seed areas of poor vegetation growth.	As required
	Prune and trim any trees and remove cuttings.	Every 2 years or as required
	Remove sediment from inlets, outlets, forebay and main basin when required.	Every 5 years or as required
Remedial Actions	Periodic measuring of the bore size	Every 3 years or as required
	Repair erosion or other damage by reseeding or re-turfing.	As required
	Realignment of rock armour	As required
	Repair/rehabilitation of inlets, outlets and overflows.	As required
	Relevel uneven surfaces and reinstate design levels.	As required

A Vortex Flow Control device is a proprietary product and therefore information regarding operations and maintenance shall be provided within the manufacturer's specification and included in the hand over documentation.

3.8.2 Pipes and Chambers.

Access points have been located at the head of each run, at a change in direction, at change of pipe size, and at regular intervals as per relevant guidance.

The appropriate health and safety equipment must be used when accessing chambers. Confined space certificates must be held by any personnel entering a chamber and appropriate permits should be obtained from the maintenance manager prior to any access. Double locked and sealed chambers must be sealed and locked correctly post maintenance operation.

The anticipated maintenance and management for pipes and chambers are outlined in Table 8.

Table 8: Typical Pipes and Chambers Maintenance Requirements

Maintenance Schedule	Required Actions	Minimum Frequency
Monitoring (To be undertaken more regularly within the first year of operation and adjusted as required)	Initial inspection should be provided as post construction CCTV survey	As required and after large rainfall events
Regular Maintenance	Inspection for evidence of poor operation via water level in chambers. If required, take remedial action.	3 monthly and 48 hours after large rainfall events.
	Check and remove large vegetation growth near pipe runs	Monthly or as required
Remedial Actions	Rod through poorly performing runs as initial remediation	As required
	If continued poor performance jet and CCTV survey poorly performing runs.	As required
	Seek advice as to remediation techniques suitable for the type of performance issue and location	As required if above does not improve performance.

Pipes are proprietary products, and the materials can vary across the site and as such where used the manufacturer's recommendations should be followed.

4.0 Foul Water Strategy

The current strategy proposes that domestic flows, from offices and welfare facilities, will be conveyed across site via a below ground pipe network to a package treatment plant, located close to the western side of the Red Line Boundary. The treated runoff will then combine with the surface water network and discharge to the Burn of Ludquharn.

The proposed rate will be determined at the detailed design phase once personnel numbers are confirmed and the package treatment plant will be designed by a specialist consultant.

All discharge is subject to approval by SEPA and it is recommended that consultation be held prior to detailed design to ascertain approval in principle.

The proposed drainage strategy plan is enclosed within *Appendix C*.

5.0 Conclusion

SLR have been appointed by SSEN to provide a Drainage Strategy, to support an outline planning application for the Netherton Hub Phase 1 development, on land at Flushing, Netherton, Aberdeenshire.

The Site is located near the village of Flushing, adjacent to the A950 Longside Road, and the nearest postcode is AB42 4TR.

Three waterbodies were identified within the site and surrounding area, including an existing unnamed ditch, the Burn of Faichfield and the Burn of Ludquharn. No public foul, surface or combined water sewers were identified within the site.

The Site is classified as greenfield and as such proposed discharge will be restricted to the Qbar rates calculated using FEH point data within Causeway Flow, based on the existing watersheds. The proposed discharge method is to the existing water bodies, identified above. The discharge locations and rates are subject to approval by SEPA.

The development has been designed in accordance with current best practice to provide adequate capacity to not allow flooding out of the network for the 1 in 30-year storm event and flood water generated for up to the critical 1 in 200-year plus 37% climate change storm event shall be constrained within the areas on site so as not to cause damage to buildings, essential services, adjoining developments and services.

Surface water runoff from highways and landscaped area will be collected and conveyed by a series of swales. This will combine with runoff from the platform below ground networks and be attenuate within detention basins prior to discharge.

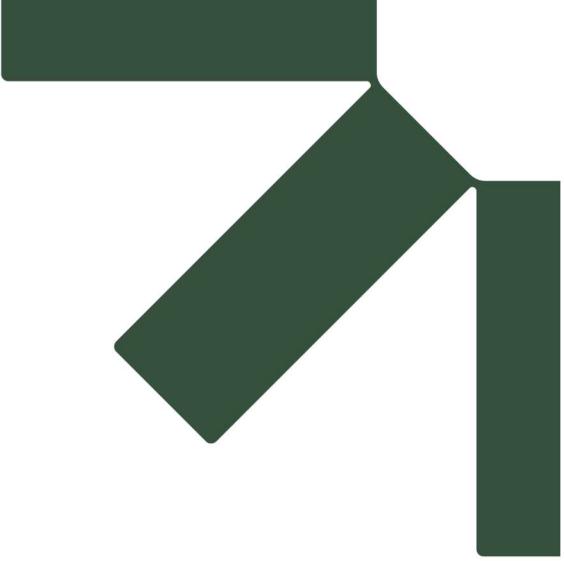

The current drainage strategy is based on the feasibility of discharging to three locations, the existing 900mm diameter pipe crossing the A590; the Burn of Faichfield at a point north of the Site; and the Burn of Ludquharn at a point west of the Site. Prior to detailed design the location and level of each discharge point will need to be confirmed.

Further hydrological investigations could be undertaken for the wider area in order to confirm flood levels of the Burn of Faichfield, for now publicly available SEPA information has been used for modelling purposes.

Domestic foul flows will be conveyed across site in a below ground pipe network to a package treatment plant before combining with surface water flows to discharge to the Burn of Ludquharn. The treatment plant is to be designed by others and is subject to approval by SEPA.

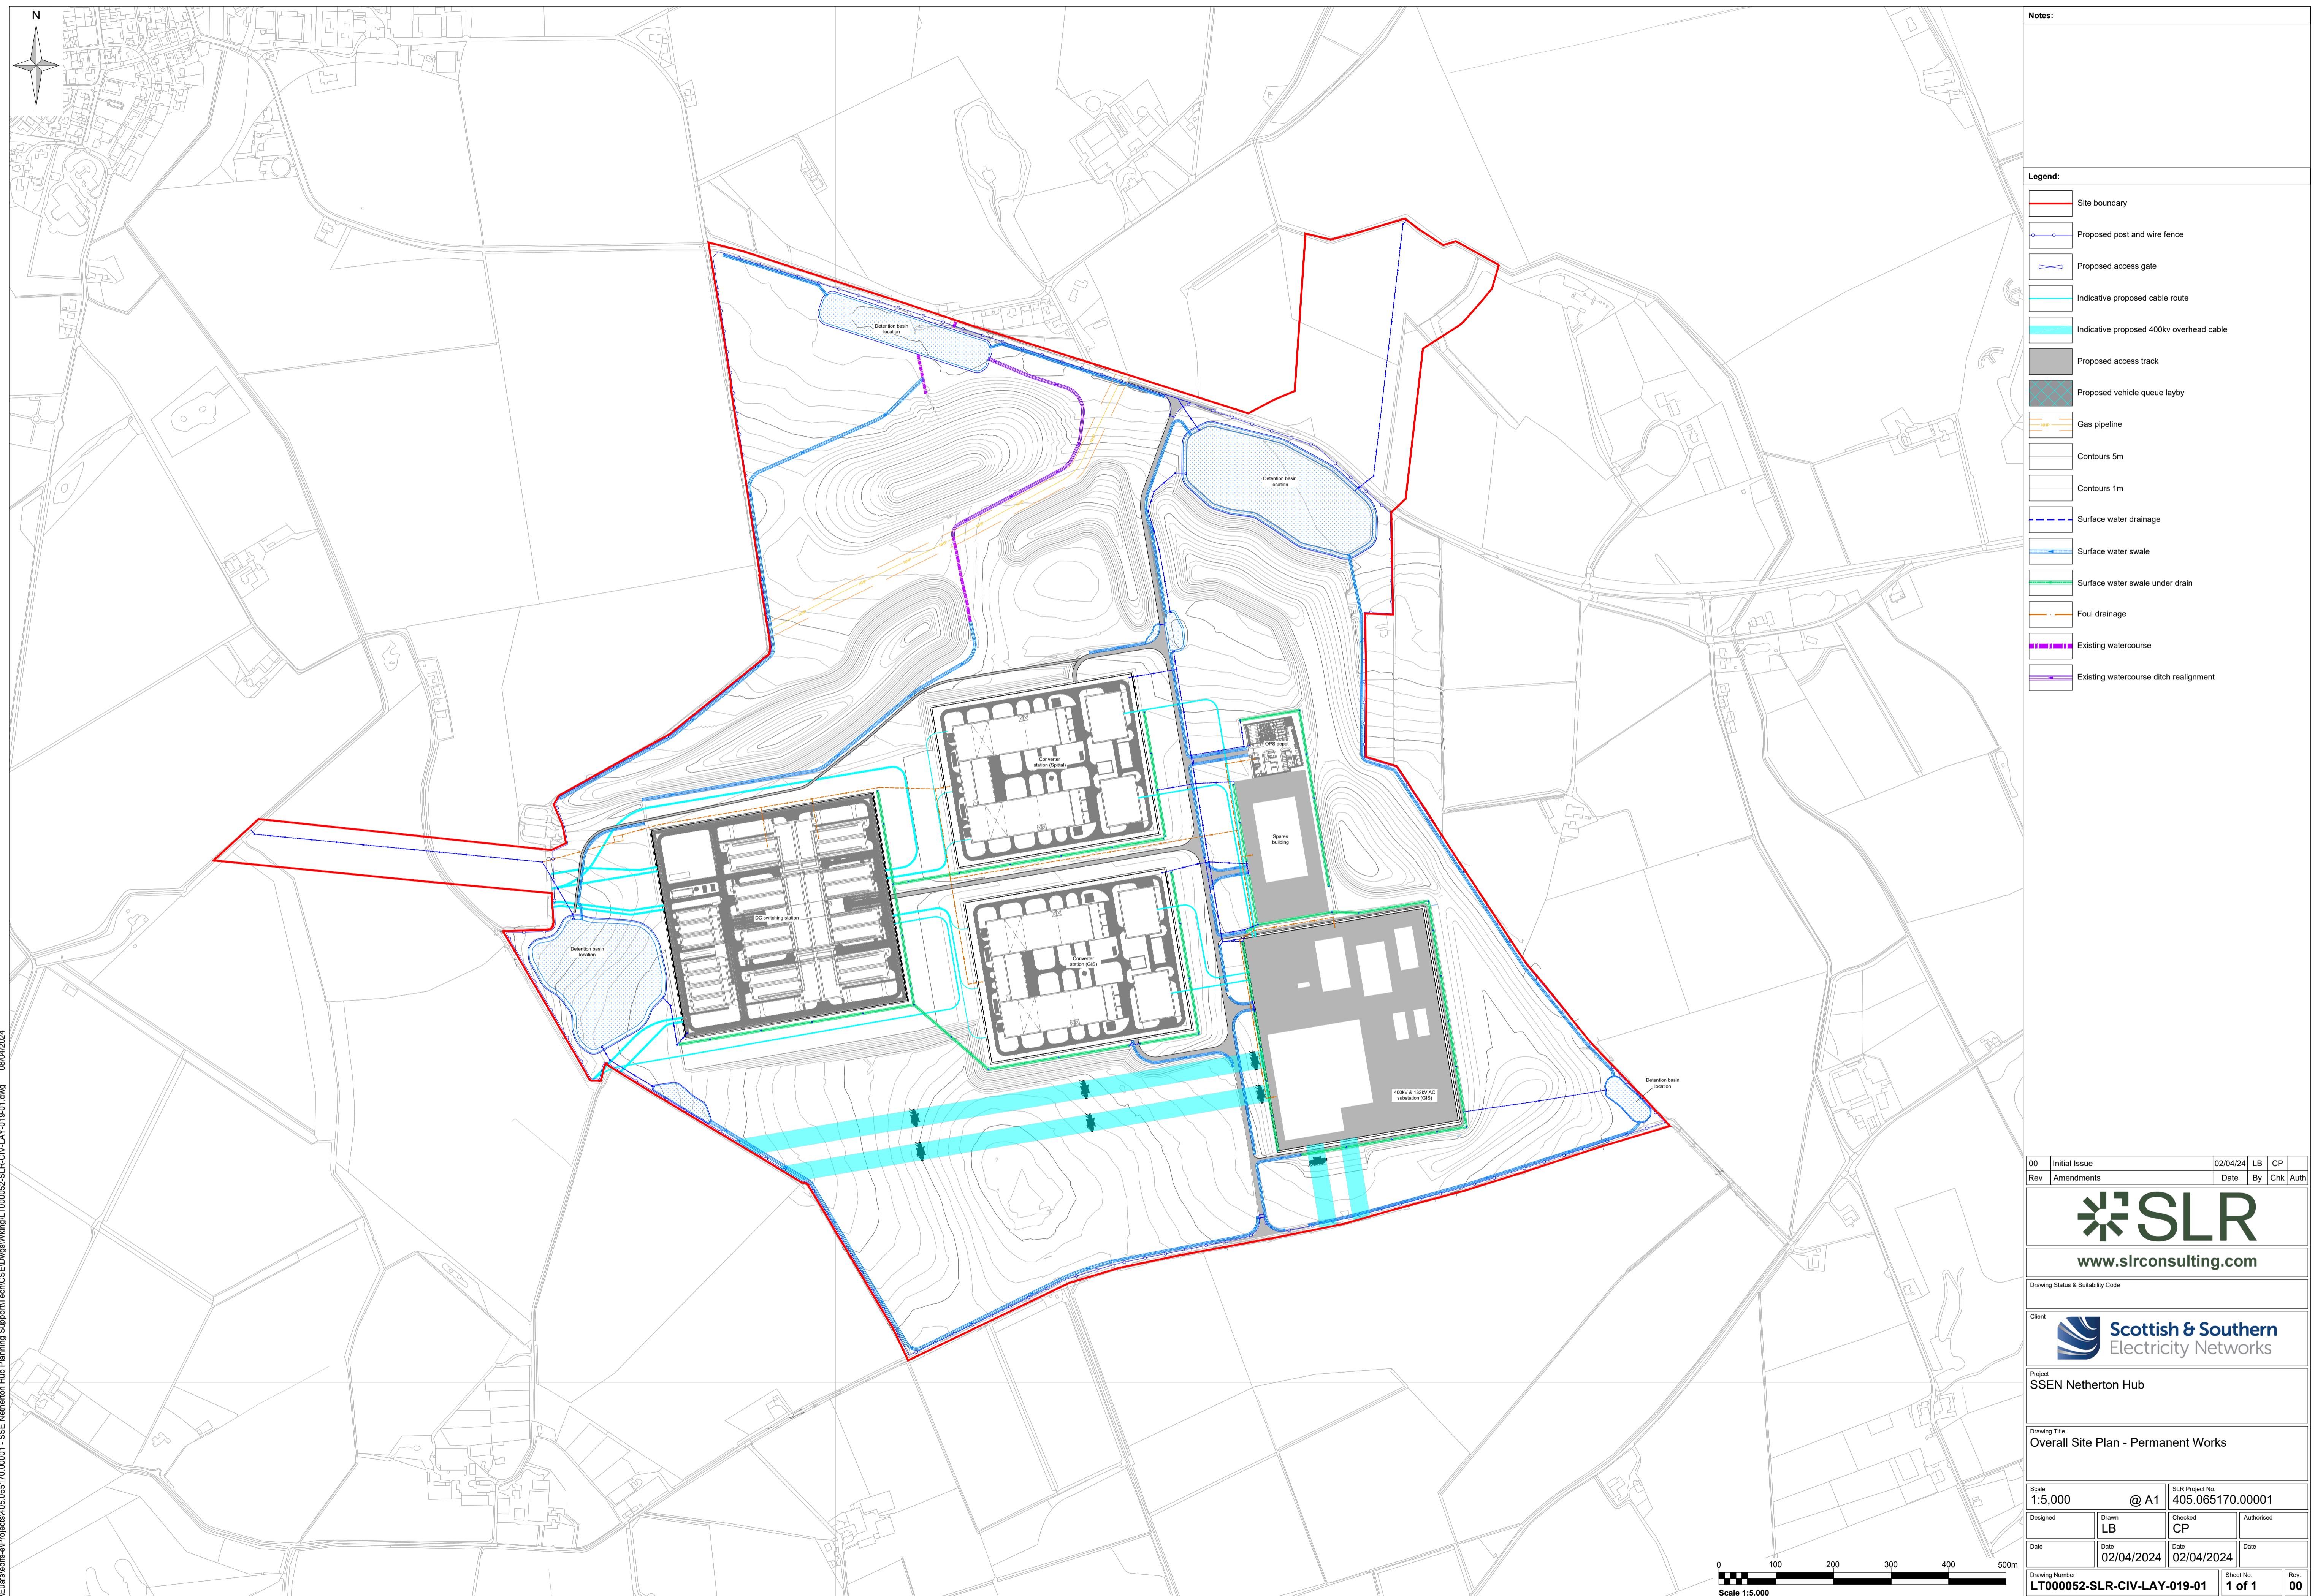

It is recommended that consultation be undertaken with SEPA early on during the detailed design stage to obtain their approval for the proposed developments, drainage strategy and final discharge methods.

GPR and Underground Utility Location Surveys are intrinsically surface based and therefore the collection and analysis of information is limited by what is currently present. Every effort has been made to remove covers where required allowing for identification and measurement of the services therein. The size and nature of service may not be able to be determined by location and/or identification of a service will not necessarily indicate whether it is live or dead.

Errors on the survey drawing may occur in relation to positions and depths in excess of 20% of the stated value. There may be services present which have not been located due to the limitations in the equipment used or site related factors which were not evident at the time of survey.

Ardmore Point advise observance to HSG47 before excavating on the site.

No liability for errors omissions or exceptions will be accepted by Ardmore Point.

Ardmore Point are not liable for any topographical survey or background mapping used in the survey drawing that has not been carried out by Ardmore Point. Any errors relating to background mapping that we have no control of are the liability of the client.

Be advised: the term end of trace signifies the last possible point of location and not the termination of the service. In these instances please proceed with caution.

- All depths are in metres unless otherwise specified.

- All dimensions are in metres unless otherwise specified.

Node 21 Online Hydro-Brake® Control

Flap Valve	x	Objective	(HE) Minimise upstream storage
Replaces Downstream Link	✓	Sump Available	✓
Invert Level (m)	27.990	Product Number	CTL-CHE-0570-3209-1450-3209
Design Depth (m)	1.450	Min Outlet Diameter (m)	
Design Flow (l/s)	320.9	Min Node Diameter (mm)	

Node 20 OUT Online Orifice Control

Flap Valve	✓	Invert Level (m)	28.110	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	3.000		

Node 18 OUT Online Orifice Control

Flap Valve	✓	Invert Level (m)	28.110	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	3.000		

Node 16 OUT Online Orifice Control

Flap Valve	✓	Invert Level (m)	28.110	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	3.000		

Node 10 Online Orifice Control

Flap Valve	✓	Invert Level (m)	28.110	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	3.000		

Node J1 Online Orifice Control

Flap Valve	x	Invert Level (m)	29.771	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	0.300		

Node J2 Online Orifice Control

Flap Valve	x	Invert Level (m)	29.611	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	0.300		

Node J3 Online Orifice Control

Flap Valve	x	Invert Level (m)	29.451	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	0.300		

Node J4 Online Orifice Control

Flap Valve	x	Invert Level (m)	29.291	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	0.450		

Node J5 Online Orifice Control

Flap Valve	x	Invert Level (m)	29.131	Discharge Coefficient	0.600
Replaces Downstream Link	x	Diameter (m)	0.450		

Node 21 Flow through Pond Storage Structure

Base Inf Coefficient (m/hr)	0.00000	Porosity	1.00	Main Channel Length (m)	60.000
Side Inf Coefficient (m/hr)	0.00000	Invert Level (m)	27.990	Main Channel Slope (1:X)	500.0
Safety Factor	2.0	Time to half empty (mins)		Main Channel n	0.030
